What is Style?

Given two corpora, the invariance between them is the content,
whereas the **variance is the style.**

<i>Style Attribute</i>	<i>Source Attribute / Sentence</i>	<i>Target Attribute / Sentence</i>
Politeness	Polite: “ Could you please send me the data?”	Impolite: “send me the data!!”
Toxicity	Offensive: “I hope they pay out the ***.”	Non-offensive: “I hope they pay what they deserve. ”
Simplicity	Expert: “Many cause dyspnea , pleuritic chest pain, or both.”	Layman: “The most common symptoms, regardless of the type of fluid in the pleural space or its cause, are shortness of breath and chest pain.”
Biasedness	Biased: “A new downtown is being developed which will bring back... ”	Neutral: “A new downtown is being developed which its promoters hope will bring back...”
Authorship	Shakespearean: “My lord, the queen would speak with you, and presently. ”	Contemporary: “My lord, the queen wants to speak with you right away. ”

Text Style Transfer

Previous work on text style transfer deals with **labelled** data.

Unsupervised Style Extraction

But what if the data is **not labelled** with respective styles?

Data

Data: Kaggle Bible Corpus (Genesis)

Invariant content, variant style!

Genesis 1:1

⋮

1533 sentences

ASV: *In the beginning God created the heavens and the earth.*

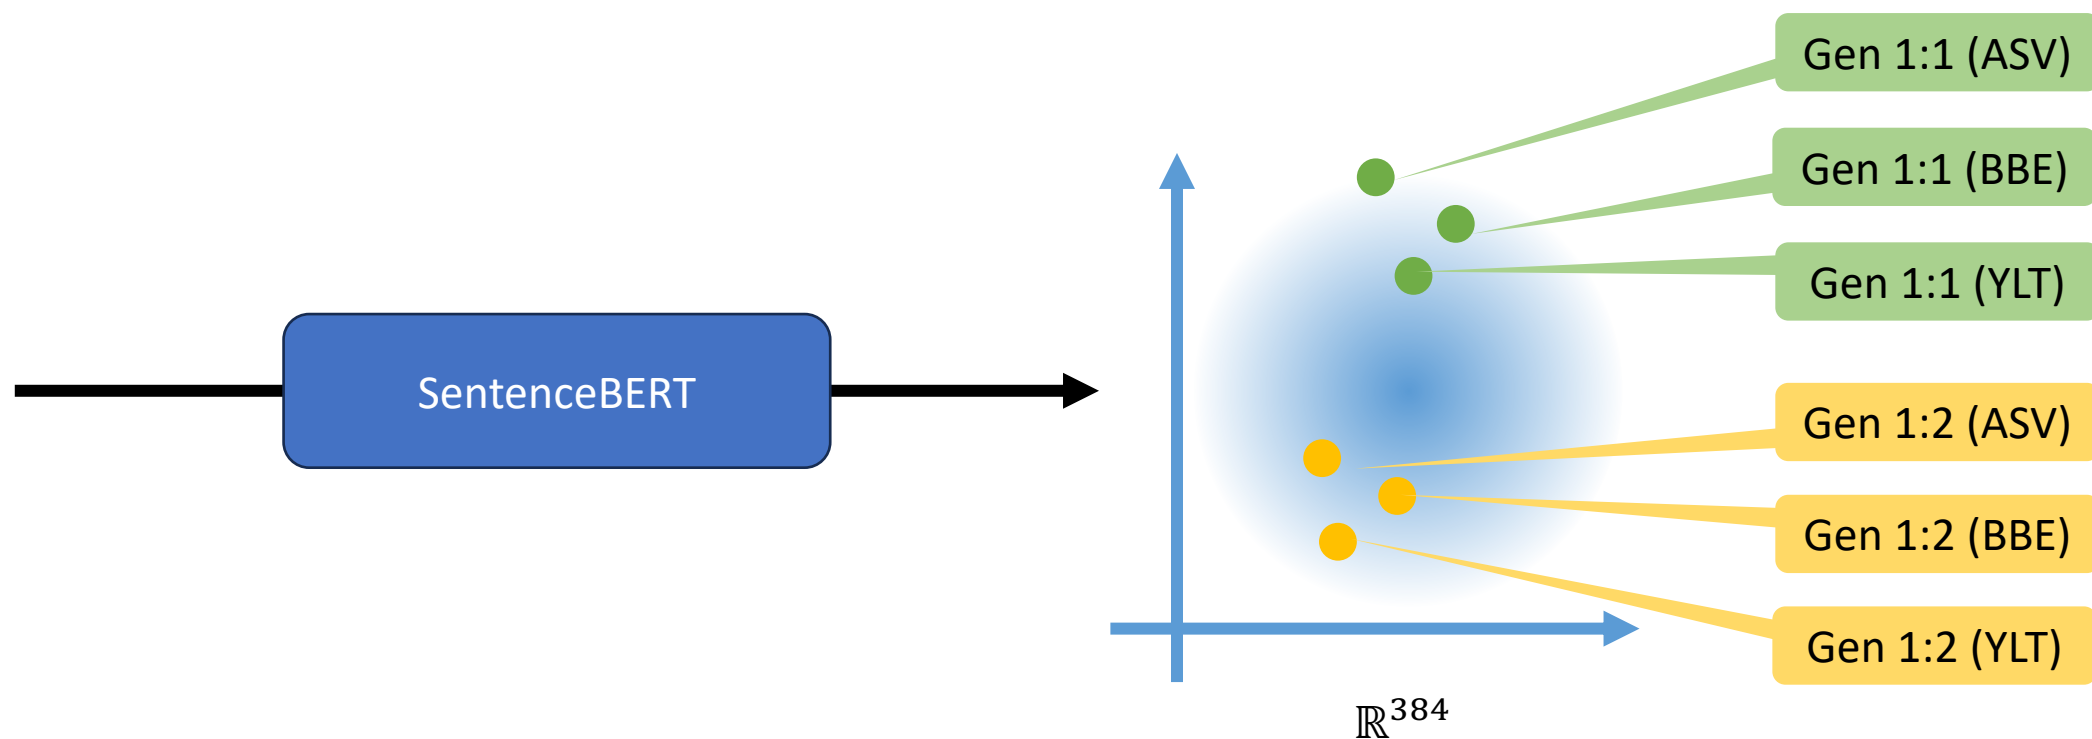

BBE: *At the first God made the heaven and the earth.*

YLT: *In the beginning of God's preparing the heavens and the earth--*

⋮

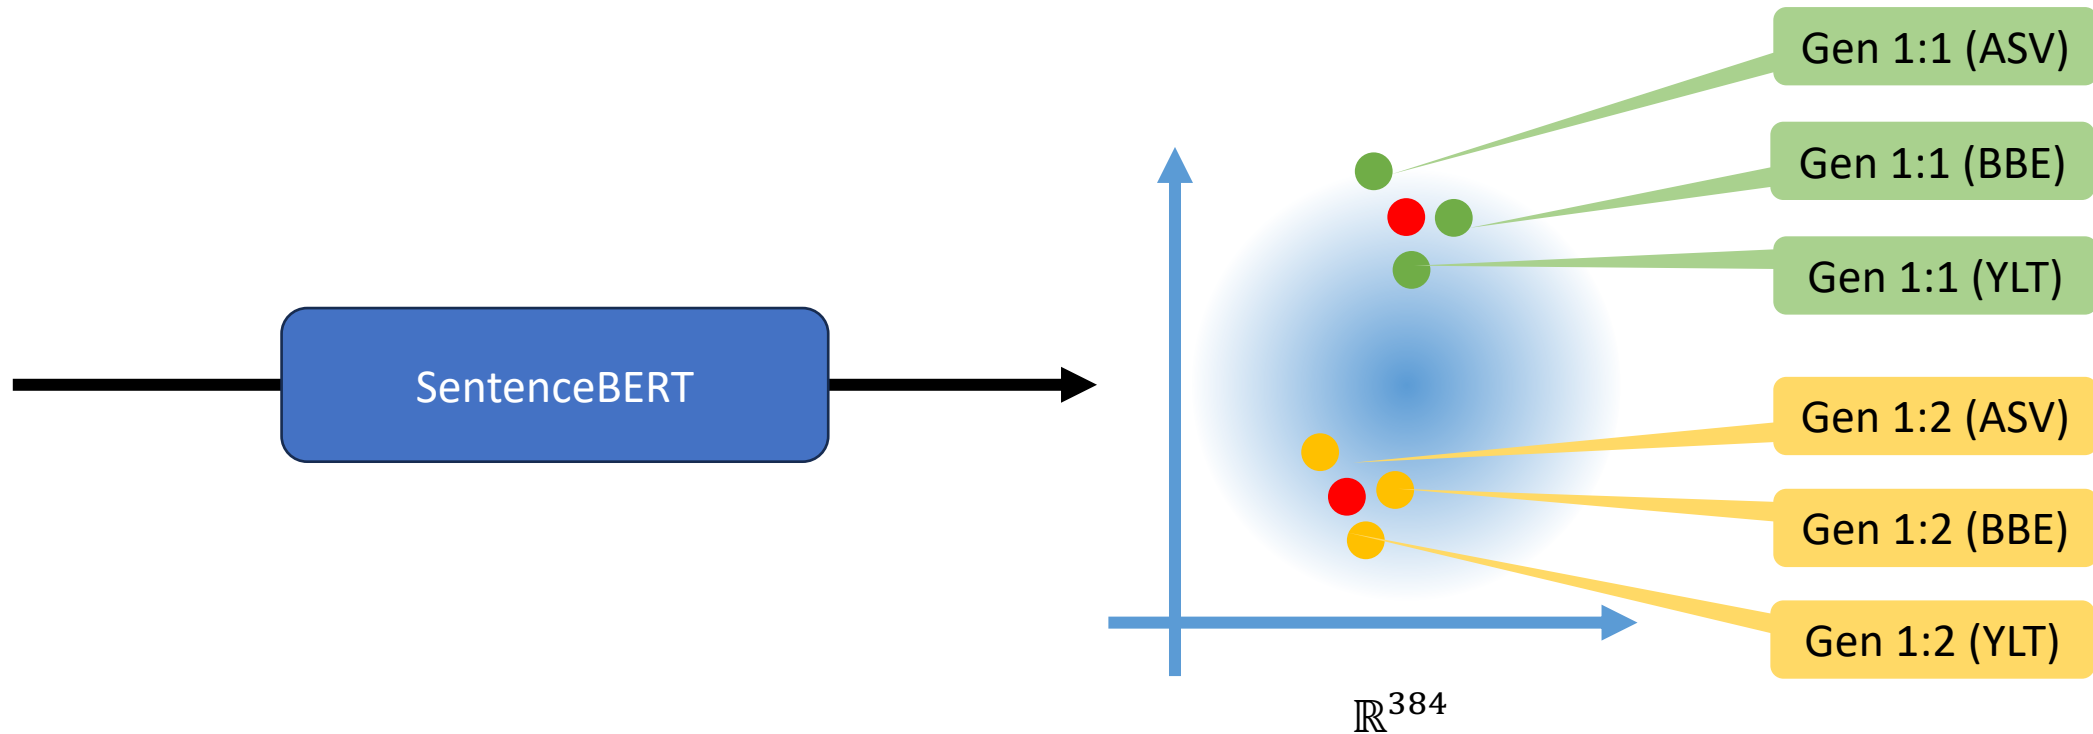

7 versions

The Model: Sentence Embedding

The Model: Sentence Embedding

Remove mean of k-nearest neighbours

The Model: Sentence Embedding

The Model: Sentence Embedding

The Model: Baseline

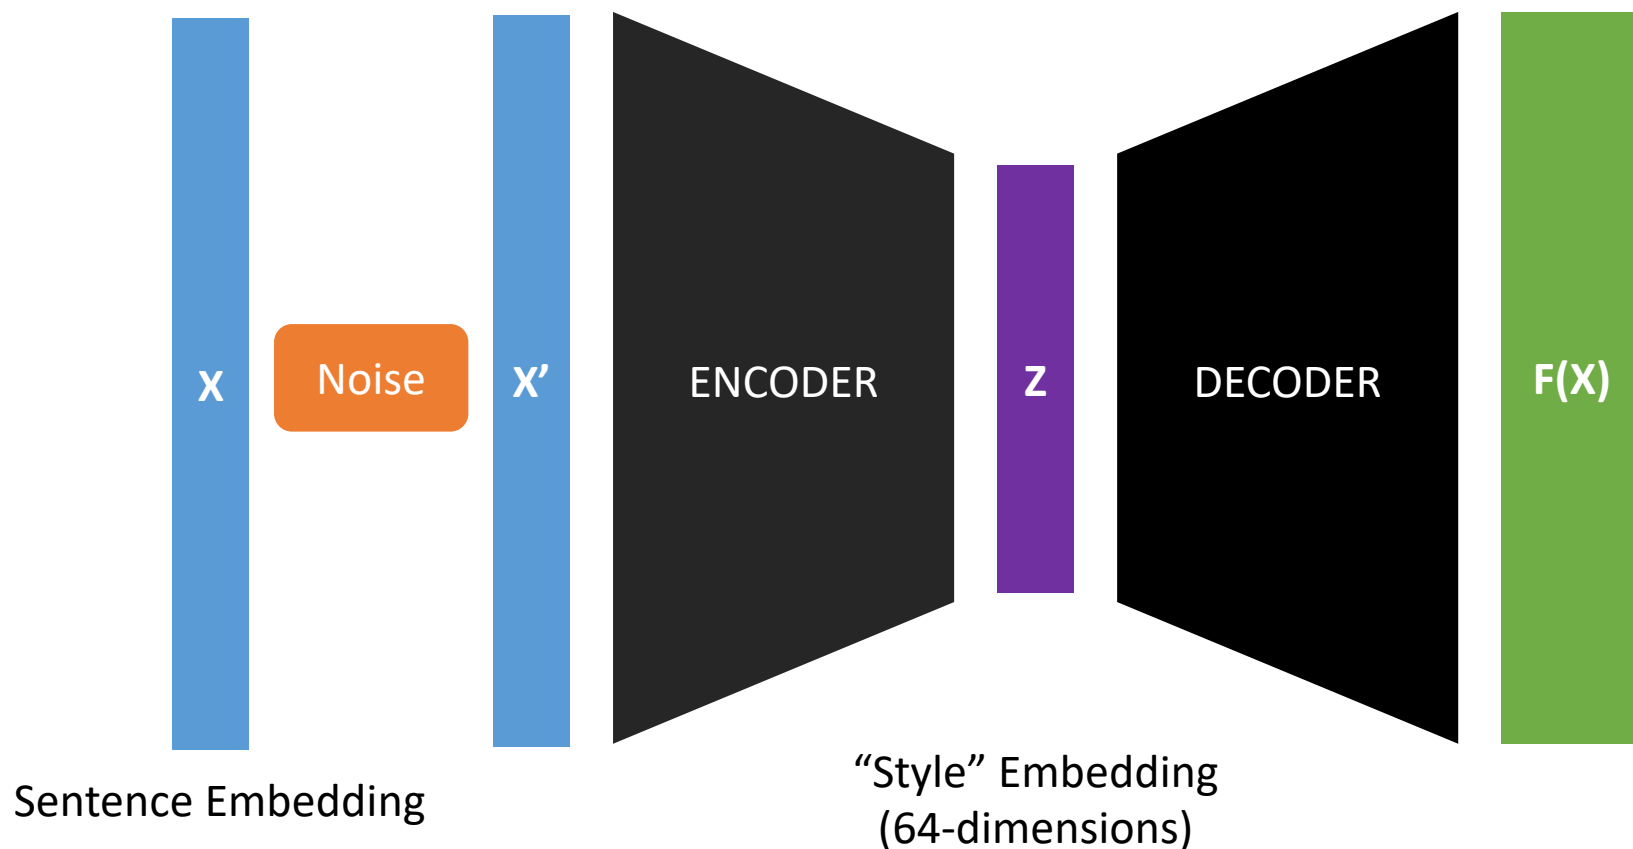

Baseline: Kmeans clustering using only the mean-removed vectors

V-Measure	Macro-Avg Acc.	Micro-Avg Acc.
0.312	0.623	0.426

The Model: Denoising AutoEncoder

Model: an Autoencoder to capture the latent style representations

The Model: Loss Function

Reconstruction Loss: $F(X)$ should be similar to mean-removed embedding

The Model: Loss Function

Positive Example Loss: Z should be similar to noise-perturbed Z

$$L_+ = (1 - Z(X)^T Z(\hat{X}))^2$$

The Model: Loss Function

Negative Example Loss: Sentences different with X should have a different Z

$$L_- = (Z(X)^T Z(Y))^2$$

The Model: Results

Baseline: Kmeans clustering using only the mean-removed vectors

V-Measure	Macro-Avg Acc.	Micro-Avg Acc.
0.402	0.751	0.480

Experiments

Hyperparameter Settings

Epoch	Batch	λ_{rec}	λ_+	λ_-	ϵ_{in}	ϵ_+	d(Z)	L Rate
50	73	1	1	1/6	5e-3	5e-2	64	1e-3

Experiments

Ablation Study

Reconstruction	Positive	Negative	V-measure
X	O	O	0.310
O	X	O	0.276
O	O	X	0.130

The loss on the **negative examples** is very important!

Discussion

Testing the Model on Different Data

- Legal Data
- Scientific Papers
- Literary Corpus

Discussion

Extracting More Data from Sentences

Fine-tune

SentenceBERT

to extract relevant information about style

Discussion

Disentanglement

Conclusion

- Our experiments demonstrate that our approach is able to learn style from sentences without supervision.
- Sentence embeddings with KNN mean-removal was used as the labels.
- An autoencoder was used, and reconstruction loss with positive-negative example loss was employed.
- The results prove significantly better than the baseline.
